Functional Servicing & Stormwater Management Report **PROPOSED TRANSPORTATION DEPOT**

1.0 INTRODUCTION

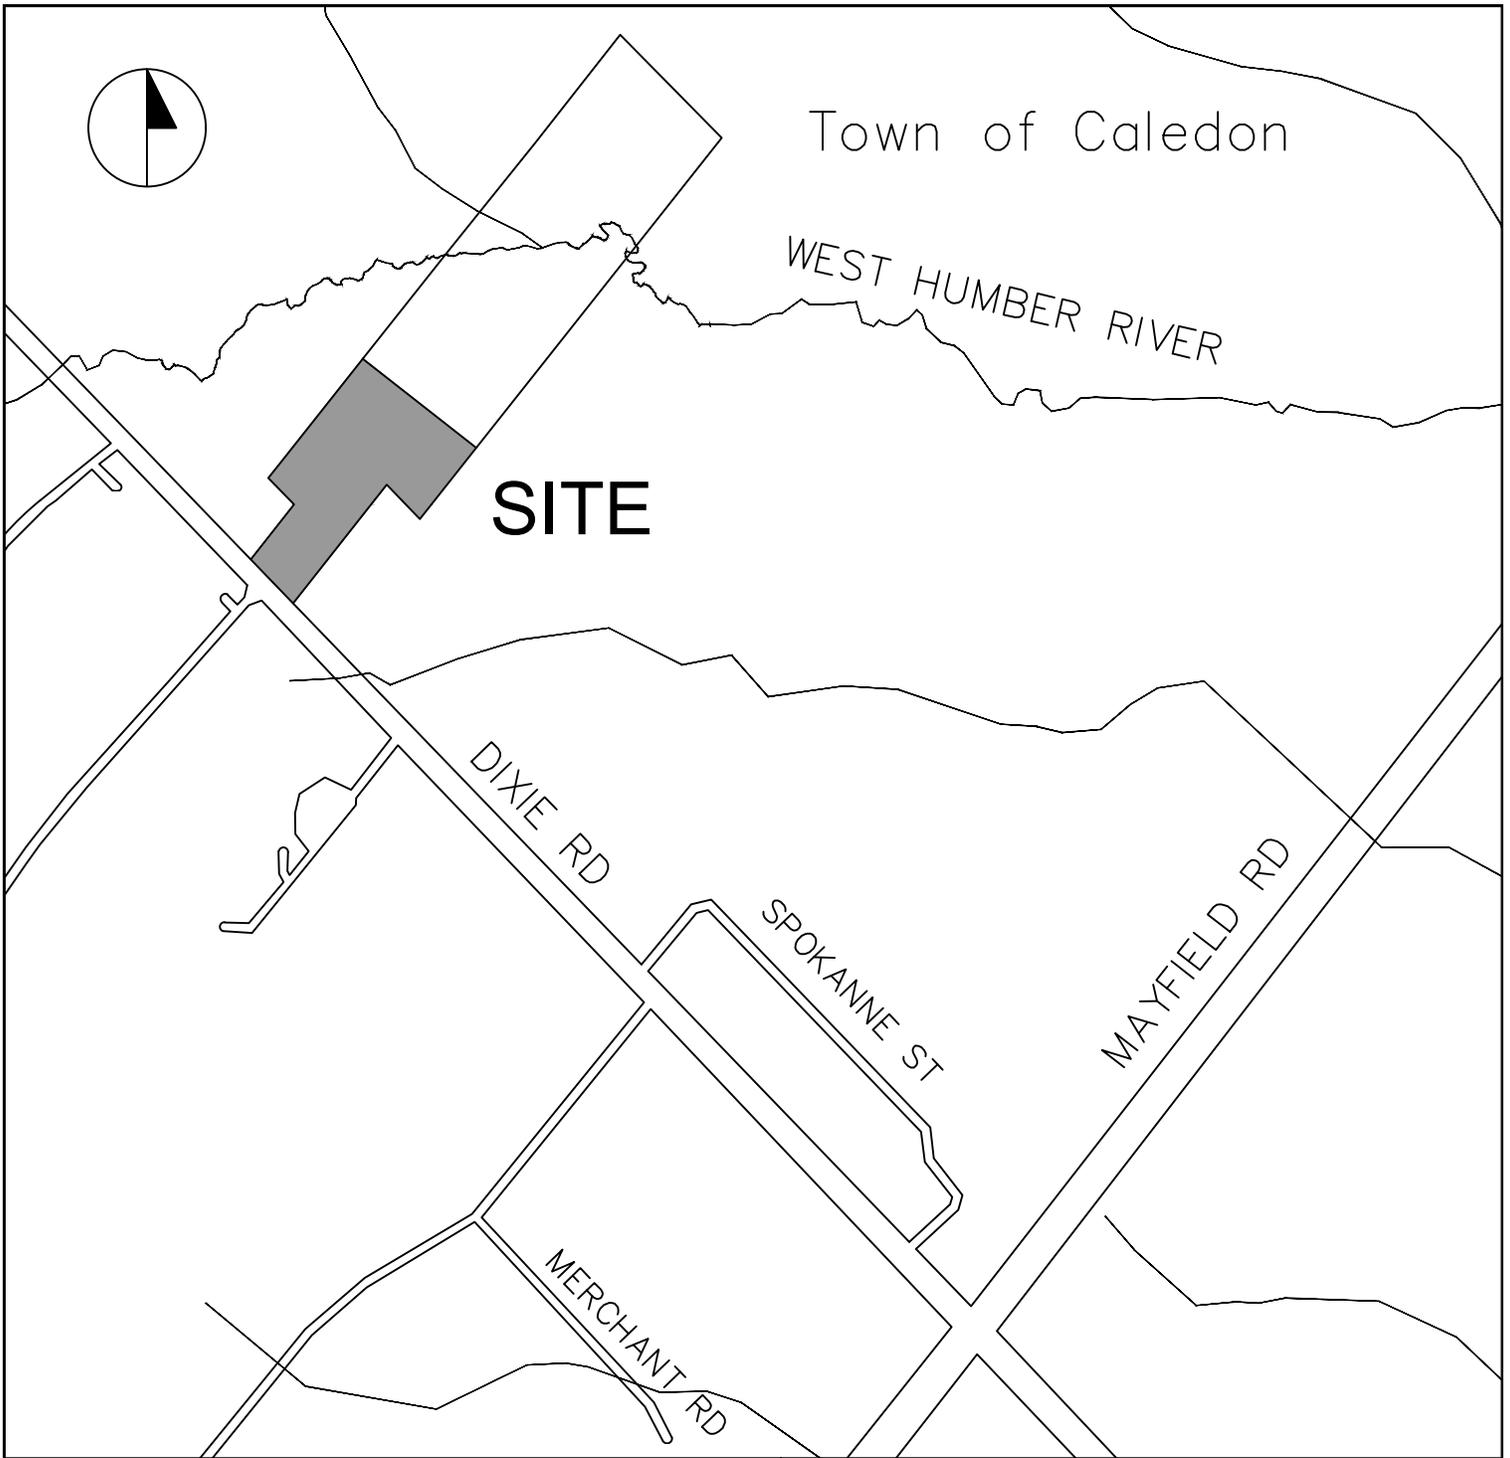

The following Functional Servicing and Stormwater Management Report has been prepared by Urban Watershed Group Limited. (UWGL), in support of the Proposed Transportation Depot located on 12363 Dixie Road in the Town of Caledon, Region of Peel. The 9.15 hectare property is located north of the Dixie Road, between Mayfield Road and Old School Road (See **Figure No. 1**), and is legally described as Part of Lot 19, Concession 4, in the Geographic Township of Chinguacousy.

The property is bounded by existing residential properties to the north, agricultural lands to the east, a landscape/garden center to the south, and Dixie Road to the west. The subject site is currently under active agricultural use, and proposed to be rezoned to permit the proposed commercial/ industrial development.

A tributary of the West Humber River watershed and its associated flood plain traverses the property and bisects the lot. To preserve the Environmental Protection Areas associated with the watercourse, the rear 7.98 ha of the total parcel shall be left as existing agricultural and natural feature land uses. The remaining 1.17 ha parcel of land outside of the Green Belt shall be the subject of the proposed development plan.

It is proposed to construct one one-storey industrial Building (office & repair building) along with 190 parking spaces which will comprise the Transportation Depot. The proposed building gross floor area is approximately 616 sq.m, of which one quarter will be office space, and the remaining area will be for the truck service/repair bays and storage space. At the front of the development truck trailer parking will be provided on an asphalt surface. Additional parking for truck cabs will be provided on a gravel surface located near the rear of the development site. Site access will be provided onto Dixie Road through a proposed commercial/ industrial driveway.

This report aims to identify the existing municipal services (storm, sanitary and water) available, and demonstrate there is sufficient capacity to accommodate the proposed development. As well, this report puts forward a stormwater management (SWM) plan which adheres to the criteria set out by the governing agencies (Town of Caledon, Toronto and Region Conservation Authority (TRCA) and Peel Region).

2.0 SANITARY SERVICING

2.1 Existing Sanitary Servicing

The site is currently vacant and believed to be un-serviced through either private septic or municipal sanitary sewers. Drawings provided by the Region of Peel indicate an existing 600mm concrete southerly flowing sanitary sewer is located within the west boulevard of Dixie Road. Plan and profiles of the existing municipal sewers can be found in **Appendix A**.

2.2 Proposed Sanitary Servicing and Peak Discharge Rates

Sanitary servicing is to be provided consistent with the Region of Peel Public Works Sanitary Sewer Design Criteria (2017). It is proposed to connect the property to the existing 600mm diameter municipal sanitary sewer on Dixie Road. A new connection is proposed via a 150mm diameter PVC sanitary lateral at minimum 2% slope complete with sampling manhole located at the limit of the road widening. The general arrangement of the proposed sanitary sewer has been indicated on the Site Servicing & Grading Plan (**Drawing 22011-SS1**).

The proposed peak sanitary discharge generated from the development has been calculated in accordance with Region of Peel Design Criteria as follows:

Proposed Sanitary Peak Discharge

Population = 50 persons/hectare
Site Area = 1.17 hectares

Equivalent Population = 50 persons/hectare x 1.17 hectares
= 58.5 (59) persons

Domestic sewage flow is based upon a unit rate of 302.8 L/capita/day, therefore:

Domestic Sewage Flow = 59 persons x 302.8L/capita/day
= 17,865.2 L/day
= 0.207 L/sec

The Harmon Peaking Factor (M) must be applied for Dry Weather Flows, and for a population below 450 persons is restricted to a maximum of 4.0:

M = $1 + 14 / (4 + P^{0.5})$
= $1 + 14 / (4 + (59/1000)^{0.5})$
= 4.30

Maximum Dry Weather Flow = 0.207 L/sec x 4
= 0.827 L/sec

Infiltration Amount = 0.0002 m³/sec/ha x 1.17 ha
= 0.000234 m³/sec
= 0.234 L/sec

$$\begin{aligned}
\text{Total Prop. Peak Discharge} &= \text{Commercial Flow} + \text{Infiltration Amount} \\
&= 0.827 \text{ L/sec} + 0.234 \text{ L/sec} \\
&= 1.061 \text{ L/sec}
\end{aligned}$$

The internal 150mm diameter pipe with a minimum fall of 2.0% has a capacity of 22.5 l/sec, and will be more than sufficient to convey the proposed flows to the municipal sewers. A Connection Demand Table has been included in **Appendix B**, in which a more detailed analysis of water and wastewater demand from the proposed development has been completed.

3.0 WATER SERVICING

3.1 Existing Water Services

The property does not have an existing municipal water service or private well. Drawings provided by the Region of Peel indicate there is an existing 400mm diameter PVC municipal feeder watermain and a 150mm diameter PVC local watermain on Dixie Road. Municipal hydrants are connected to the 400mm diameter watermain. Plan and profiles of the existing municipal watermain can be found in **Appendix A**.

3.2 Proposed Water Services & Peak Water Demands

It is proposed to provide a new fireline/domestic connection per Region of Peel Standard 1-6-4. A new connection to the 150mm diameter municipal watermain of Dixie Road is proposed via a 150mm diameter PVC water service installed cut in tee. The proposed domestic service size is 50mm, and will branch off the proposed 150mm diameter water service connection immediately before the limit of the road widening. A new water meter shall be provided within the mechanical room of the building. The general arrangement of the fire and domestic water services has been indicated on the Site Servicing & Grading Plan (**Drawing 22011-SS1**).

3.2.1 Domestic Flow

Domestic water demands have been estimated using the Region of Peel Public Works Watermain Design Criteria (2010). For the 59 persons (calculated for proposed peak sanitary flow), average ICI consumption rate of 300 L/day/cap has been used. A max day factor of 1.4 and a peak hour factor of 3.0 have been applied.

Peak Water Demand

$$\begin{aligned}
\text{Daily Water Consumption} &= 59 \text{ persons} \times 300 \text{ L/capita/day} \\
&= 17,700 \text{ L/day} \\
&= 0.205 \text{ L/sec}
\end{aligned}$$

$$\begin{aligned}
\text{Maximum Daily Demand} &= \text{Daily Water Consumption} \times \text{Max Day Factor} \\
&= 17,700 \text{ L/day} \times 1.4 \\
&= 24,780 \text{ L/day} \\
&= 0.287 \text{ L/s}
\end{aligned}$$

$$\begin{aligned} \text{Peak Hourly Demand} &= \text{Daily Water Consumption} \times \text{Peak Hour Factor} \\ &= 17,700 \text{ L/day} \times 3.0 / 24 \text{ hours/day} \\ &= 2,212.5 \text{ L/hour} \\ &= 0.615 \text{ L/s} \end{aligned}$$

3.2.2 Fire Flow Demands

Regional standards require watermains to be sized to meet a minimum pressure of 140 KPA (20 PSI) under the maximum day demand plus fire flow. The fire flow requirements for the building have been estimated using the NFPA Fire Underwriters Survey's Water Supply for Public Fire Protection (1999). The proposed 736 sq.m gross floor area, has been used in calculation of fire flow requirements for combustible building construction with a high occupancy hazard classification (repair garage) and a fully supervised sprinkler system. The total required fire flow demand has been calculated as 4,255 L/min (70.91 L/s). Detailed calculations of the fire flow demand are included in **Appendix B**, along with a Connection Demand Table.

The proposed development shall be connected to the local 150mm diameter municipal watermain. Hydrant flow testing of this local watermain is not possible, as the existing hydrants are connected to the 400mm diameter municipal feeder main in front of the site. Region of Peel staff should confirm the adequacy of the watermain to service the development based on regional watermain modelling.

4.0 STORMWATER MANAGEMENT

4.1 Stormwater Management Criteria

The property is located within a regulated area of the Toronto and Region Conservation Authority (TRCA) Watershed. A portion of the property is within the Regulatory floodplain of a tributary of the West Humber River at an elevation of 256.80 metres. The existing runoff from the property is primarily conveyed by sheet flow directly into the watercourse across the agricultural lands.

The proposed structure will have a finished floor elevation of 263.15, and therefore be sufficiently situated above the Regional Floodplain elevation.

The policies set out in the TRCA Stormwater Management Criteria (August 2012), outline the below applicable SWM criteria for the development which are to be followed:

- **Flood Protection**
 - Post to Pre for up to and including 100-year storms (Town of Caledon)
 - Unit Flow Rates for pre-development conditions (TRCA)
- **Erosion Control**
 - Extended detention of 25mm event for 48 hours (TRCA)
 - At minimum retain 5mm on site (TRCA and Town of Caledon)
- **Water Quality**
 - Enhanced Level of Protection (80% Total Suspended Solids Removal) per MECP criteria (TRCA and Town of Caledon)
- **Water Balance / Groundwater Recharge**
 - Site specific water balance analyses and maintenance of recharge (TRCA and Town of Caledon)

The criteria above will be defined in detail and addressed within the succeeding sections of the report.

4.2 Site Statistics

The total development area outside of the Greenbelt is 1.17 ha and is comprised of agricultural land. The land generally slopes in a north easterly direction, across a change in grade of approximately 3.25 meters with an average slope of 2.7%. The existing time of concentration using the airport method is considered approximately 30 minutes.

The proposed 0.11 ha SWM Facility will be located within the Greenbelt limits, but outside of any site specific environmental or natural hazard features identified. In the existing conditions, the SWM facility has a total 0.46 ha catchment area of agricultural land within the Greenbelt which shall be considered as such for the purposes of the SWM analysis.

The drainage characteristics and imperviousness of the remaining lot outside the development limits will not be altered, and are therefore excluded from the SWM analysis. Runoff from the 1,554 sq.m north and east perimeter landscape area identified on the post-development drainage area plan (**Figure No. 3**), is to be conveyed via sheet flow directly toward the watercourse at an uncontrolled rate, and similarly will not be considered in the catchment area as they will not generate an increase in runoff from the existing conditions.

The proposed SWM Facility has been considered to have a runoff coefficient of 1.0 during all storm events.

An external drainage of 0.23 ha from the adjacent lot to the south is also observed to traverse the subject property, will be allowed to flow through the site overland unimpeded. The external area has been considered in SWM analysis were doing so will not result in a non-conformant condition for the property should the neighbouring site self-contain this drainage.

The subject site's existing and proposed conditions have been summarized in the following tables:

Existing Condition (Figure No. 2)

Land Use	Area	C	AC
Development Area	11,769	0.25	2,942.3
SWM Facility Ex. Catchment Area	4,622	0.25	1,155.5
External Drainage Area	2,344	0.25	586.0
Total Existing Conditions Area	18,735	0.25	4,683.8

Proposed Conditions (Figure No. 3)

Land Use	Area	C	AC
Building Area	616	0.90	554.4
Impervious Area	8,536	0.90	7,682.4
Pervious Area	942	0.25	235.5
SWM Facility Area	1,120	1.00	1,120.0
SWM Facility Ex. Catchment Area	3,502	0.25	875.5
External Drainage Area	2,344	0.25	586.0
Total Catchment Area	17,060	0.65	11,053.8
Uncontrolled Pervious Area	1,675	0.25	418.8
Total Proposed Conditions Area	18,735	0.61	11,472.6

$$\begin{aligned}
 \% \text{ Impervious of Catchment Area} &= (616 + 8,536 + 1,120) / 17,060 \\
 &= 10,272 \text{ sq.m} / 17,060 \text{ sq.m} \\
 &= 60.2\%
 \end{aligned}$$

TRCA and Town criteria require runoff controls be implemented to maintain the peak flow rate generated from the property under existing conditions.

4.3 Native Soils Conditions and Water Table Elevations

The native soil generally comprises an average 150 topsoil layer underlain by a native sandy silt deposit (up to depths of 0.05 to 0.8mbgs). A sandy silt till to sandy clayey silt was encountered beneath the sandy silt and extending to the full exploration depth (4.5 to 6.0 mbgs), as described in the Small-Scale Hydrogeological Assessment (May 2023) by A & A Environmental Consultants Inc. Excerpts from this report have been included in **Appendix C**. Three (3) monitoring wells were installed on site at depths between 4.5 and 6.0 meters. Groundwater was observed in monitoring well MW-1, MW-2 and MW-3 at depths of 1.71 and 0.411 and 0.61 meters respectively, on January 13, 2023 after a 3 month period.

Based on literature the estimated coefficient of permeability for the native silt and clay material is 10^{-5} cm/sec. Using the correlation of hydraulic conductivity to percolation time presented in Appendix C of the CVC Low Impact Development Stormwater Management Planning and Design Guide, an infiltration rate for the native soils can be calculated as follows:

$$\begin{aligned} \text{Hydraulic Conductivity} &= 6e-11 \times (\text{Infiltration Rate})^{3.7363} \\ \text{Infiltration Rate} &= (\text{HC} / 6e-11)^{1/3.7363} \\ &= (10^{-5} / 6e-11)^{1/3.7363} \\ &= 30 \text{ mm/hr} \\ \text{Design Infiltration Rate} &= \text{Measured Infiltration Rate} / \text{Safety Factor} \\ &= 30 \text{ mm/hr} / 2.5 \\ &= 12 \text{ mm/hr} \end{aligned}$$

The design infiltration rate of 12 mm/hr is near the MECP recommended 15mm/hr for infiltration SWM facilities, and shall be used for LID sizing calculations, where applicable.

4.4 Flood Protection

As per the TRCA's Stormwater Management Criteria, the subject site falls within the Sub-Basin 36 of the Humber River watershed, and the formulas presented in Table E.1 shall be used. The 0.23 ha external drainage area shall be excluded from allowable release rate calculations to ensure the SWM control devices do not become oversized should the drainage patterns on the adjacent land be altered in the future. The 100-year allowable flow rate for the 14,716 sq.m (17,060 sq.m – 2,344 sq.m) total catchment area located within the property limits has been calculated below:

$$\begin{aligned} Q_{100\text{-YR}} &= [29.912 - 2.316\ln(A)] \times A \\ &= [29.912 - 2.316\ln(1.4716 \text{ ha})] \times 1.4716 \text{ ha} \\ &= 29.02 \text{ L/s/ha} \times 1.4716 \text{ ha} \\ &= 42.7 \text{ L/s} \end{aligned}$$

The unitary flow rates for the 2-year to 100-year events have also been calculated using the provided formulas and are summarized below:

Return Period	Unit Flow Rate Equation	Unit Flow Rate
100-Year	$Q = 29.912 - 2.316 * \ln(A) \times A$	42.7 L/s
50-Year	$Q = 26.566 - 2.082 * \ln(A) \times A$	37.9 L/s
25-Year	$Q = 22.639 - 1.741 * \ln(A) \times A$	32.3 L/s
10-Year	$Q = 17.957 - 1.373 * \ln(A) \times A$	25.6 L/s
5-Year	$Q = 14.652 - 1.136 * \ln(A) \times A$	20.9 L/s
2-Year	$Q = 9.506 - 0.719 * \ln(A) \times A$	13.6 L/s

The 2-year existing release rates from the subject development has also been calculated below utilizing the Town of Caledon IDF curve (Guelph O.A.C) and a 30 minute time of concentration for comparison.

$$\begin{aligned}
 I_{2\text{-YEAR}} &= 1070 / (t + 7.85)^{0.8759} & Q_{2\text{-YR, PRE}} &= CIA / 3600 \\
 &= 1070 / (30 + 7.85)^{0.8759} & &= 0.25 \times 44.4 \text{ mm/hr} \times 14,716 \text{ sq.m} / 3600 \\
 &= 44.4 \text{ mm/hr} & &= 45.4 \text{ L/s}
 \end{aligned}$$

As with the unit flow rates, the 2-year to 100-year existing release rates, are also summarized below:

Return Period	Rainfall Intensity	Existing Peak Flow Rate
100-Year	115.3 mm/hr	117.8 L/s
50-Year	102.5 mm/hr	104.7 L/s
25-Year	90.4 mm/hr	92.4 L/s
10-Year	74.6 mm/hr	76.2 L/s
5-Year	60.9 mm/hr	62.3 L/s
2-Year	44.4 mm/hr	45.4 L/s

The catchment area must be controlled to no more than a peak release rate of 13.6 L/s under a 2-year storm event, and 42.7 L/s under a 100-year storm event in accordance with the TRCA's SWM criteria. The TRCA Unit Flow Rate criteria yield a lower peak flow rate for each design storm, and therefore meeting this criterion will satisfy the Town requirements as well.

Runoff from the site is to be collected by proposed catchbasins, and controlled by a proposed standpipe upstream of the proposed outfall. Detention storage will be provided on the surface above the proposed catchbasin tops for the required reduction is peak flow rates as discussed in the following sections.

4.4.1 SWM Detention Volumes

Detention storage volumes will be provided within a proposed flood protection pool of the dry pond component in the SWM facility. The Modified Rational Method has been utilized to determine the required stormwater detention volumes to satisfy the peak flow rate control criteria developed above. Refer to **Appendix D - Figure Nos. 4 to 10** for the 2-year through 100-year storm event calculations. Detention storage requirements to be provided as part of the proposed design are as follows:

Design Storm	TRCA Storage Requirement	Town of Caledon Storage Requirement	Provided Storage Volume
2-year	284.8 cu.m	200.2 cu.m	406.5 cu.m
5-year	403.7 cu.m	284.8 cu.m	520.7 cu.m
10-year	483.1 cu.m	345.3 cu.m	625.5 cu.m
25-year	590.6 cu.m	426.2 cu.m	696.0 cu.m
50-year	661.8 cu.m	483.5 cu.m	703.6 cu.m
100-year	743.7 cu.m	545.0 cu.m	748.3 cu.m

4.5 Stormwater Volume and Erosion Control

TRCA criteria require stormwater runoff from a 25mm rainfall event volume be captured and retained on site through infiltration, evapotranspiration, re-use, etc to the maximum extent practical with a minimum of 5mm. Any remaining volume from the 25mm event must be detained on site for a period of 48 hours. For the 11,769 sq.m development site the minimum required retention and detention volumes are calculated as follows:

$$\begin{aligned} \text{25mm Erosion Control Volume} &= 11,769 \text{ sq.m} \times 25\text{mm} \\ &= 294.2 \text{ cu.m} \end{aligned}$$

$$\begin{aligned} \text{5mm Retention Volume} &= 11,769 \text{ sq.m} \times 5\text{mm} \\ &= 58.8 \text{ cu.m} \end{aligned}$$

Any proposed infiltration features on site will be drastically constrained by the existing shallow groundwater table, believed to be within less than 1 meter of existing grade in the vicinity of the proposed SWM Facility as discussed in **Section 4.3**. Extended detention is proposed to be utilized per TRCA's erosion control criteria to overcome the sites reduced retention potential.

4.5.1 5mm Retention Strategy

Impervious surfaces, such as the building roof and asphalt parking, can be commonly considered to evaporate up to 20% of frequent rainfall events (rainfall events 5mm or less comprises roughly 50% of the average annual rainfall volume). The first 1mm (5mm x 20%) of rainfall onto impervious surfaces will be considered to evaporate as follows:

$$\begin{aligned}\text{Impervious Surface Evaporation Volume} &= \text{Building Roof Area} + \text{Asphalt Parking} \times 1\text{mm} \\ &= (616 \text{ sq.m} + 8,536 \text{ sq.m}) \times 1\text{mm} \\ &= 9.1 \text{ cu.m}\end{aligned}$$

Pervious surfaces, such as landscaping/ sod, are also considered to retain frequent rainfall events through evapotranspiration and infiltration. The additional retention volume provided from these surfaces is calculated as follows:

$$\begin{aligned}\text{Pervious Surface Retention Volume} &= \text{Landscaped Area} \times 5\text{mm} \\ &= (942 \text{ sq.m} + 1,675 \text{ sq.m}) \times 5\text{mm} \\ &= 13.1 \text{ cu.m}\end{aligned}$$

The initial abstraction volume available on site is thus calculated as 22.2 cu.m (9.1 cu.m + 13.1 cu.m). An additional 37.0 cu.m of stormwater retention is provided from the proposed infiltration basin (refer to **Section 4.6.3**). Therefore, a total of 59.2 cu.m (22.2 cu.m + 37.0 cu.m) will be retained on site to meet the 5mm criteria.

4.5.2 24 to 48 hour Extended Detention

The remaining runoff volume from a 25mm rainfall event which is not retained on site must be collected and controlled on site for a gradual release over a 48 hour period. The required extended detention volume has been calculated as 294.2 cu.m.

The falling head equation for a constant storage area (Equation 4.10 of the 2003 MOE Stormwater Planning and Design Manual), has been used to verify the extended detention criteria will be met based on the proposed SWM Facility geometry. Detailed calculations have been included in **Appendix E**, and concluded the proposed stand pipe must be made up of five (5) 25mm diameter orifices at an equal elevation to achieve a 46.3 hour extended detention period. To achieve the necessary volumes and draw down time the active storage within the SWM Pond facility must have a constant surface area of 1,120 sq.m at a total depth of 0.26m.

4.6 SWM Control Structure Sizing

The proposed SWM facility must provide the required 2-year through 100-year peak flow rate controls developed in **Section 4.3**, and 48 hour extended detention for the volume from the 25mm event per the volume reduction criteria developed in **Section 4.4**.

The stand pipe structure configuration necessary to achieve the extended detention criteria was found to limit the release rates below the 2-year allowable of 13.6 L/s, and a larger diameter orifice has been provided above the extended detention pool to achieve the flood protection criteria. An additional overland flow weir has been provided above the 10-year ponding elevation to allow larger storms to discharge at a higher rate. A stage storage discharge table (**Appendix E**) has been prepared to identify the total release rate from the SWM facility and associate water level during each design storm.

The extended detention pool will be provided within the bottom portion of the dry pond, between the elevations 259.20 and 259.46m. The bottom of the extended detention pool will start above the spring line of the five (5) 25mm diameter perforations on the proposed stand pipe.

The 2-year to 10-year storage will be provided below the overflow weir between the elevations 259.46 and 259.78m. The open top of the 125mm diameter standpipe will be installed at the elevation 259.50m and act as the secondary orifice.

The 25-year to 100-year storage will be provided above the overflow weir between the elevations 259.78m and 259.80m. The top of proposed SWM Facility berm shall be constructed to a minimum elevation 260.00m.

The stand pipe outlet will discharge to existing grade at an elevation of 258.28 and will be above the 100-year floodplain of the downstream watercourse, which is at an elevation of 256.03m.

4.7 Water Quality Control

Storm drainage for this site discharges to the natural environment via the SWM facility outlet to the West Humber River. A multi-component analysis has been developed for the proposed site to meet the TRCA and Town water quality objectives. The overall site shall provide an Enhanced Level (80% TSS Removal) of treatment per MECP criteria. Runoff from the proposed parking lot shall be pre-treated by an Oil Grit Separator to removal any spilled oils or grease, and to provide initial TSS removal. The proposed SWM Facility will provide final polishing via a sediment forebay and infiltration facility.

4.7.1 Oil Grit Separator

An Oil Grit Separator (OGS) has been proposed to treat stormwater runoff from the proposed storm sewer prior to discharge into the SWM Facility to ensure spilled oils or grease is adequately contained. A proposed FD-5HC OGS unit has been certified through ETV testing protocols to provide a TSS removal efficiency of 45% minimum and capture of >90% of annual runoff volumes. A detailed size report for this system has been included in **Appendix F**.

4.7.2 Forebay Pre-Treatment

A sediment forebay is proposed at the upstream end of the SWM facility to promote the settling of sediments, and reduce long-term maintenance requirements for the remainder of the SWM facility. The forebay will have a maximum permanent depth of 0.85 metres. The minimum recommended forebay length is calculated utilizing by determining the settling length per Equation 4.5 of the 2003 MOE Stormwater Planning and Design Manual. A 25mm design storm shall be considered for forebay sizing, the resulting rainfall intensity and peak flow rate determine utilizing Equation 4.9.

$$\begin{aligned} I_{25\text{mm}} &= 43(C) + 5.9 & Q_{25\text{mm}} &= CIA / 3600 \\ &= 43(0.65) + 5.9 & &= 0.65 \times 33.9 \text{ mm/hr} \times 17,060 \text{ sq.m} / 3600 \\ &= 33.9 \text{ mm.hr} & &= 161 \text{ L/s} \end{aligned}$$

r = length-to-width ratio of forebay (minimum 2:1)

Q_p = peak flow rate from pond during design quality storm

V_s = particle settling velocity (recommended 0.0003 m/s)

$$\begin{aligned} \text{Minimum Forebay Settling Distance} &= \sqrt{rQ_p/V_s} \\ &= (3 \times 0.161 / 0.0003)^{1/2} \\ &= 32.8 \text{ m} \end{aligned}$$

A total volume of the forebay has been design to accommodate 10-years of sediment accumulation based on the contributing drainage area and Table 6.3 of the 2003 MOE Stormwater Planning and Design Manual. For the contributing drainage area with an overall imperviousness of 60.2% the forebay will accumulate and annual loading of 2.2 cu.m/ ha. Thus, total forebay volume of 37.4 cu.m (2.2 cu.m/ha x 1.7 ha x 10 yrs), is required.

The proposed forebay geometry will be 33m long, 0.85m deep with a top and bottom width of 16m and 4m, respectively, and the available volume is calculated below:

$$\begin{aligned} \text{Forebay Volume} &= [(4\text{m} + 16\text{m})/2] \times 0.85\text{m} / 2 \times 33\text{m} \\ &= 140 \text{ cu.m} \end{aligned}$$

Therefore, the proposed forebay will provide more than adequate settling length and volume to provide the necessary pre-treatment to the SWM facility.

4.7.3 Infiltration Basin

The proposed infiltration basin has been designed to reduce the flow of sediment latent runoff from the site to achieve 80% TSS removal from captured stormwater runoff. The water quality storage requirements for the proposed facility have been determined utilizing Table 3.2 of the MOE Stormwater Planning and Design Manual (2003). For the 1.7 ha contributing drainage area with an overall imperviousness of 60.2% the infiltration basin can provide 70% TSS removal if 21.7 cu.m/ha of storage is provided. The provided infiltration basin must have a volume of 36.9 cu.m (21.7 cu.m/ha x 1.70 ha).

To achieve the desired water quality objectives the infiltration facility will be filled with 150mm deep layer of 50mm clear stone beneath a 100mm deep sand filter layer. The total volume of the 528 sq.m infiltration facility is calculated below:

$$\begin{aligned} \text{Infiltration Basin Storage Volume} &= (\text{Clear Stone Depth} \times \text{Void Ratio} + \text{Sand Filter Depth} \times \text{Void Ratio}) \\ &\quad \dots \times \text{Infiltration Basin Footprint} \\ &= (150\text{mm} \times 0.40 + 100\text{mm} \times 0.10) \times 528 \text{ sq.m} \\ &= 37.0 \text{ cu.m} \end{aligned}$$

The draw down time and footprint of the infiltration basin have also been checked to verify the facility will operate as intended.

$$P = \text{infiltration rate (mm/hr)}, \quad t = \text{draw down time (hrs)}, \quad V = \text{Retention volume (m}^3\text{)} \quad n = \text{void ratio}$$

$$\begin{aligned} \textbf{Equation 4.2} \quad \text{depth} &= Pt \\ &= 12 \text{ mm/hr} \times 20.8 \text{ hr} \\ &= 250 \text{ mm} \end{aligned}$$

$$\begin{aligned} \textbf{Equation 4.3} \quad \text{Area} &= 1000V / (Pnt), \\ &= 1000 \times 36.9 / (12 \times 0.28 \times 24) \\ &= 458 \text{ sq.m} \end{aligned}$$

Therefore, the proposed 250mm deep and 528 sq.m infiltration basin will infiltrate the full 36.9 cu.m within a 20.8 hour period. The infiltration basin will be provided beneath the extended detention pool between the elevations 258.95 and 259.20m.

The observed seasonal high water table elevation in the vicinity of the SWM Facility was recorded as 258.60masl. Due to constraints to maintain the existing grade on site, further raising the bottom of the facility to provide additional vertical separation above the water table is not feasible.

4.7.4 Suspended Solids Removal

The combined TSS removal rate for two features which operate in series ($R = A + B - (A \times B)$), has been utilized in to determine the net TSS removal efficiency of the site and verify the net 80% TSS removal criteria will be met for the proposed development.

Water Quality Device	TSS Removal Efficiency	Notes
Oil Grit Separator	45%	per ETV Certification
Infiltration Basin	70%	per MOE Table 3.2
Net TSS Removal	83.5%	

The proposed treatment train for the site will provide an 83.5% reduction in the annual post-development sediment loading.

4.7.5 Construction Phase Erosion and Sediment Control

A temporary silt fence as per OPSD 219.130 is to be installed along all property lines where there is a risk of sediment runoff onto the adjacent property during construction. Double row silt fence shall be provided along the limits of the development site where runoff may discharge directly to the watercourse. This fencing shall be installed prior to site grading and shall be maintained throughout the construction period. A mud mat per Town standards shall be constructed at the onset of the works at proposed site entrance to prevent sediment from being tracked onto the street, and street sweeping shall be carried out as necessary. A concrete washout station shall be set up by the contractor to manage waste water from the cleaning of tools and equipment

Temporary interceptor swales (complete with sock check dams) are to be used to capture and convey runoff from the destabilized site into sediment basins (sized to provide 125 cu.m/ha settling storage volume). The complete erosion control plan has been illustrated on Dwg. **22011-ESC1**, and shall be inspected and maintained until all exposed soil is stabilized on the site.

4.8 Water Balance Analysis

4.8.1 Pre-Development Conditions

The existing level of groundwater recharge for the proposed 11,769 sq.m development area has been estimated using the model presented in the Ministry of the Environment's (MOE), Stormwater Management Planning and Design Manual (2003), and calibrated for rainfall data from the Bowmanville Mostert weather station and local ground cover.

Station Information: Orangeville MOE, Ontario					
Latitude:	43°55'06 N	Longitude:	80°05'11 W	Elevation:	411.50 m
Climate ID:	6155790	WMO ID:		TC ID:	
Average Annual Precipitation			901.5 mm		
Annual Events > 5mm	57	Annual Events 0 – 5mm	94	Total Annual Events	151

The Thornthwaite-Mather methodology has been applied to determine the potential evapotranspiration, infiltration and runoff from the site, considering the local climate and land use types. To determine the developments effects on the water balance pre- and post- development models have been prepared with the following consideration:

- The pre- and post-development topography of pervious areas is flat at an average 2-4% slope;
- The native soil underlying the site are understood to be predominately a silt and clay till material of decent drainage qualities. In-situ soils investigations completed are further discussed in **Section 4.3**;
- The land use type of the site considered cultivated; and,
- Impervious areas will contribute no infiltration, and be subject to a 20% evaporation factor.

Hydrological cycle component values used to calculate the pre- and post-development water balance are summarized below. Detailed calculations of each value are included in **Appendix G**.

Hydrological Cycle Component Values	Precipitation	Evapo-transpiration	Runoff	Infiltration
Pre/Post-Development Pervious Surfaces	901.6	472.3	171.7	257.6
Impervious Surfaces (Buildings, Driveway, etc.)	901.6	180.3	721.3	0.0

The average annual pre-development infiltration loss is then calculated as:

$$\begin{aligned} \text{Pre-Development Infiltration} &= \text{Pervious Area} \times \text{Average Annual Infiltration Depth} \\ &= 11,769 \text{ sq.m} \times 0.2576 \text{ m} \\ &= 3,032 \text{ cu.m} \end{aligned}$$

$$\begin{aligned} \text{Post-Development Infiltration} &= \text{Pervious Area} \times \text{Average Annual Infiltration Depth} \\ &= 2,617 \text{ sq.m} \times 0.2576 \text{ m} \\ &= 674 \text{ cu.m} \end{aligned}$$

$$\begin{aligned} \text{Infiltration Deficit} &= 3,032 \text{ cu.m} - 674 \text{ cu.m} \\ &= 2,357 \text{ cu.m/ year} \end{aligned}$$

Therefore, the infiltration deficit volume of 2,357 cu.m per year must be restored in the post-development scenario through Low Impact Development (LID) techniques. To offset the reduction in infiltration levels, an infiltration trench is proposed within the SWM facility. This feature will allow stormwater runoff from frequent storm events to infiltrate into the ground surface to mitigate the impacts to the annual water balance.

4.8.2 Mitigation Plan

The available volume of from impervious surface towards the SWM facility has been calculated below, considering the total pavement and building area of 9,152 sq.m is captured and conveyed to the facility via the storm sewer system.

$$\begin{aligned} \text{Runoff Available for Infiltration} &= [\text{Total Impervious Area} \times \text{Annual Rainfall Depth} \times \text{Evaporation Factor}] \\ &= [9,152 \text{ sq.m} \times 0.9016\text{m} \times 0.80] \\ &= 6,601 \text{ cu.m / yr} \end{aligned}$$

By capturing and infiltrating 36% (2,357 cu.m / 6,601 cu.m) of this net surplus, the infiltration deficit for the site will be sufficiently offset. A 2.5mm rainfall event is consider approximately 36% of average annual rainfall (based on the Percentage of Rainfall VS Daily Rainfall Depth relationship for the Toronto area), and will meet this criterion. Therefore, to ensure sufficient retention storage within the SWM facility, a retention volume of 22.9 cu.m (9,152 sq.m x 0.0025m), must be provided.

The proposed infiltration trench within the SWM Facility has a retention volume of 37 cu.m and will be adequate to meet the groundwater recharge criteria.

4.9 Catchbasin Inlet Capacity Analysis

The inlet capacity of the proposed catchbasin frames has been analyzed during a 100-year storm event based on the typical OPSD 400.020 configuration (0.121 sq.m inlet area), and assuming 50% of the inlet area is blocked to ensure the proposed storm sewer system can adequately capture and convey runoff to the SWM Facility. The maximum ponding depths ovetop each catchbasin are summarized below based on the contributing drainage area.

Structure ID	Drainage Area (sq.m)	100-year Peak Flow Rate (L/s)	Maximum Ponding Depth (cm)	50% Blockage Depth (cm)
CB1	108	6	0.0	0.1
CB2	1,234	67	3.9	15.4
DCB3	1,590	87	1.6	6.4
DCB4	3,050	166	5.9	23.6
CBMH1	740	40	1.4	5.5
CBMH2	840	46	1.8	7.1
CB5	980	53	2.4	9.7

4.10 Inspection & Maintenance

It is encouraged that emergent species of vegetation (tall grasses which can withstand prolonged wet periods) be incorporated within the SWM facility, to increase survivability and reduce the need for regular trimming. Vegetation density should be maintained at a minimum of 80% coverage and replanted as necessary. Regular watering may be required during the first two years to establish the desired vegetation coverage.

The owner is to carry out annual inspections of the SWM facilities (during the early spring or late fall), for erosion or accumulated sediment and debris. Removal of sediment, regrading and replanting is to occur during a dry period immediately in any areas which are observed to be inundated with sediment (accumulated depth greater than 100mm). Cleaning of the sediment forebay is recommended when the depth of accumulated sediment results in a forebay depth below 0.5m.

Inspection of the outlet weir and standpipe should also be completed at the same time for blockage or obstructions. Additional inspections of all facilities should be carried out following periods of intense rainfall (>25mm in 24 hours). Signs of erosion are to be repaired with appropriate measures (such as rip-rap or replanting), during a dry period immediately upon being observed.

The infiltration basin sub-drain should be inspected from the provided clean-outs for accumulated sediment and flushed via hydro-vacuum truck if depth of sediment greater than 25mm are observed. A maintenance valve connecting the infiltration basin sub-drain to the SWM facility outlet has been provided to help facilitate draining the pond during maintenance activities. The valve should be kept in the closed position during normal operating conditions.

Vehicle and equipment access to the SWM facility can be provided through the proposed curb depression. A temporary mud-mat and access road can be constructed between the asphalt surface and work area to use of permit heavy equipment and prevent sediment tracking off-site as required. Future work within the SWM facility needs to be pre-approved and permitted by TRCA, and all site conditions should be returned to the approved conditions upon completion.

5.0 CLOSURE

The proposed Stormwater Management Plan demonstrates that the development will meet the established criteria with respect to stormwater management set forth in governing documents. The SWM facility will control the release rate to the existing levels for all storms up to and including the 100-year event. On-site stormwater detention storage has been provided up to a quantity of 748.3 cu.m in order to facilitate the proposed SWM controls, included peak flow control and 24 hour extended detention of the first 25mm of any rainfall event. Water quality control is to be primarily provided by the infiltration basin which receives runoff from the proposed impervious surfaces, and will be augmented by an oil grit separator for spill protection. Water balance criteria will be achieved through infiltration which occurs within the infiltration basin of the SWM facility.

The existing municipal water supply will be utilized to provide domestic and fire water servicing to the proposed building. A proposed sanitary service connection to existing municipal infrastructure constructed to address sanitary wastewater generated from the development.

In conclusion, the proposed servicing and stormwater management plan demonstrates that the development will meet the established criteria set forth in governing documents and the sufficient infrastructure will be provided to support the site.

Please do not hesitate to contact us with any questions pertaining to the enclosed.

Yours truly,

Urban Watershed Group Limited

Weir Discharge Below Centroid

$$Q = Cd((10.12(h/d)^{1.975} - 2.66(h/d)^{3.78}))d^{5/2}$$

Q = Discharge rate through circular weir (L/s)
 Cd = coefficient of discharge = 0.555 + (1/110(h/d)) + 0.041(h/d)
 h = height of water over weir bottom (m)
 d = diameter of circular weir (m)

Input Parameters

Orifice 1 diameter: 25 mm x5
 Orifice 2 diameter: 125 mm
 Weir Breadth: 1 m
 Weir Length: 4 m
 Orifice 1 Cd: 0.63
 Orifice 2 Cd: 0.80
 Weir Coef. kt: 2.6
 1

Orifice Discharge Above Centroid

$$Q = Cd \cdot A_o \cdot \sqrt{2g \cdot h}$$

Q = discharge rate through orifice (L/s)
 Cd = coefficient of discharge (0.63 for orifice plate or 0.80 for orifice tube)
 A_o = cross sectional area of orifice (sq.m)
 g = gravitational constant (9.81 m/s²)
 dh = height of water over orifice centroid (m)

Bottom of storage elevation: 259.20 masl
 Invert of Orifice 1 elevation: 259.19 masl
 Invert of Orifice 2 elevation: 259.50 masl
 Overflow weir elevation: 259.78 masl

Dry pond storage footprint = 1120.0 sq.m
 Dry pond storage water surface = 1296.0 sq.m
 Storage depth = 0.80 m
 Storage porosity = N/A

Calculated Parameters

Orifice 1 Springline: 259.20 masl
 Orifice 2 Centroid: 259.50 masl
 Orifice 1 Area: 0.0025 sq.m
 Orifice 2 Area: 0.0123 sq.m

Broad Crest Weir Discharge

$$Q = 0.55 \times C \times L \times H^{1.5} \times kt \times 1000$$

Q = Discharge over broad crest weir (L/s)
 Cw = Weir Coefficient
 L = Weir Length (m)
 H = upstream water level over weir (m)

I. First Defense® by Hydro International

Introduction

The First Defense® is an enhanced vortex separator that combines an effective and economical stormwater treatment chamber with an integral peak flow bypass. It efficiently removes total suspended solids (TSS), trash and hydrocarbons from stormwater runoff without washing out previously captured pollutants. The First Defense® is available in several model configurations (refer to *Section II. Model Sizes & Configurations*, page 4) to accommodate a wide range of pipe sizes, peak flows and depth constraints.

Operation

The First Defense® operates on simple fluid hydraulics. It is self-activating, has no moving parts, no external power requirement and is fabricated with durable non-corrosive components. No manual procedures are required to operate the unit and maintenance is limited to monitoring accumulations of stored pollutants and periodic clean-outs. The First Defense® has been designed to allow for easy and safe access for inspection, monitoring and clean-out procedures. Neither entry into the unit nor removal of the internal components is necessary for maintenance, thus safety concerns related to confined-space-entry are avoided.

Pollutant Capture and Retention

The internal components of the First Defense® have been designed to optimize pollutant capture. Sediment is captured and retained in the base of the unit, while oil and floatables are stored on the water surface in the inner volume (Fig.1).

The pollutant storage volumes are isolated from the built-in bypass chamber to prevent washout during high-flow storm events. The sump of the First Defense® retains a standing water level between storm events. This ensures a quiescent flow regime at the onset of a storm, preventing resuspension and washout of pollutants captured during previous events.

Accessories such as oil absorbent pads are available for enhanced oil removal and storage. Due to the separation of the oil and floatable storage volume from the outlet, the potential for washout of stored pollutants between clean-outs is minimized.

Applications

- Stormwater treatment at the point of entry into the drainage line
- Sites constrained by space, topography or drainage profiles with limited slope and depth of cover
- Retrofit installations where stormwater treatment is placed on or tied into an existing storm drain line
- Pretreatment for filters, infiltration and storage

Advantages

- Inlet options include surface grate or multiple inlet pipes
- Integral high capacity bypass conveys large peak flows without the need for "offline" arrangements using separate junction manholes
- Proven to prevent pollutant washout at up to 500% of its treatment flow
- Long flow path through the device ensures a long residence time within the treatment chamber, enhancing pollutant settling
- Delivered to site pre-assembled and ready for installation

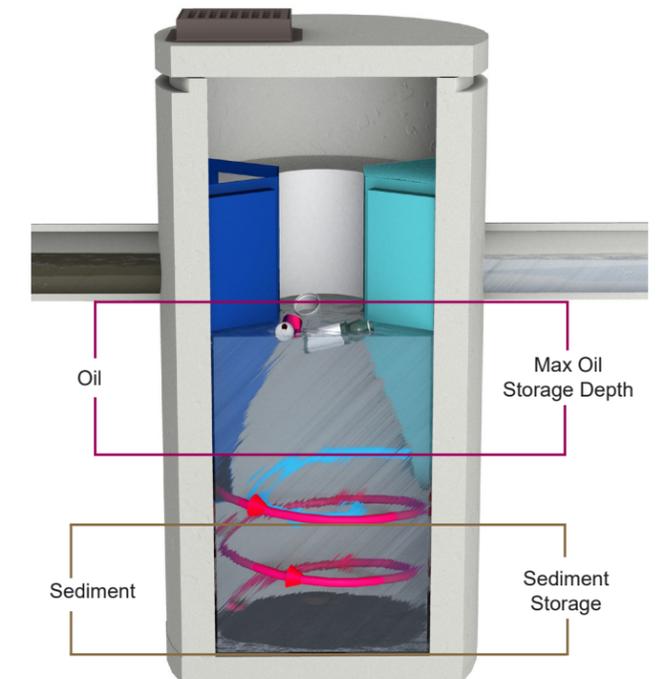

Fig.1 Pollutant storage volumes in the First Defense®.

II. Model Sizes & Configurations

The First Defense® inlet and internal bypass arrangements are available in several model sizes and configurations. The components of the First Defense®-4HC and First Defense®-6HC have modified geometries as to allow greater design flexibility needed to accommodate various site constraints.

All First Defense® models include the internal components that are designed to remove and retain total suspended solids (TSS), gross solids, floatable trash and hydrocarbons (Fig.2a - 2b). First Defense® model parameters and design criteria are shown in Table 1.

First Defense® Components

³Minimum distance for models depends on pipe diameter.

III. Maintenance

Overview

The First Defense® protects the environment by removing a wide range of pollutants from stormwater runoff. Periodic removal of these captured pollutants is essential to the continuous, long-term functioning of the First Defense®. The First Defense® will capture and retain sediment and oil until the sediment and oil storage volumes are full to capacity. When sediment and oil storage capacities are reached, the First Defense® will no longer be able to store removed sediment and oil. Maximum pollutant storage capacities are provided in Table 1.

The First Defense® allows for easy and safe inspection, monitoring and clean-out procedures. A commercially or municipally owned sump-vac is used to remove captured sediment and floatables. Access ports are located in the top of the manhole.

Maintenance events may include Inspection, Oil & Floatables Removal, and Sediment Removal. Maintenance events do not require entry into the First Defense®, nor do they require the internal components of the First Defense® to be removed. In the case of inspection and floatables removal, a vactor truck is not required. However, a vactor truck is required if the maintenance event is to include oil removal and/or sediment removal.

Maintenance Equipment Considerations

The internal components of the First Defense®-HC have a centrally located circular shaft through which the sediment storage sump can be accessed with a sump vac hose. The open diameter of this access shaft is 15 inches in diameter (Fig.3). Therefore, the nozzle fitting of any vactor hose used for maintenance should be less than 15 inches in diameter.

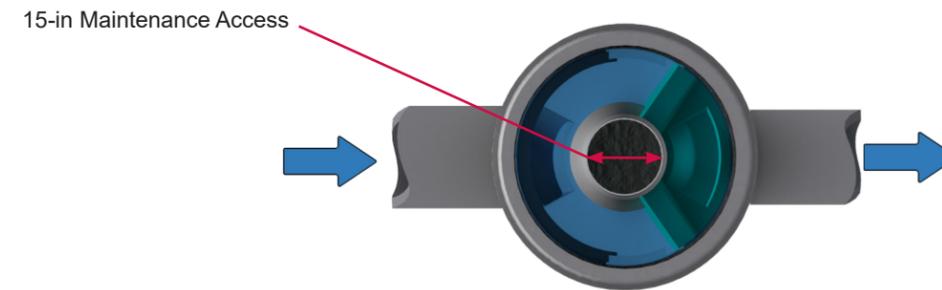

Fig.3 The central opening to the sump of the First Defense®-HC is 15 inches in diameter.

Determining Your Maintenance Schedule

The frequency of clean out is determined in the field after installation. During the first year of operation, the unit should be inspected every six months to determine the rate of sediment and floatables accumulation. A simple probe such as a Sludge-Judge® can be used to determine the level of accumulated solids stored in the sump. This information can be recorded in the maintenance log (see page 9) to establish a routine maintenance schedule.

The vactor procedure, including both sediment and oil / floatables removal, for a 6-ft First Defense® typically takes less than 30 minutes and removes a combined water/oil volume of about 765 gallons.

Inspection Procedures

1. Set up any necessary safety equipment around the access port or grate of the First Defense® as stipulated by local ordinances. Safety equipment should notify passing pedestrian and road traffic that work is being done.
2. Remove the grate or lid to the manhole.
3. Without entering the vessel, look down into the chamber to inspect the inside. Make note of any irregularities. Fig.4 shows the standing water level that should be observed.
4. Without entering the vessel, use the pole with the skimmer net to remove floatables and loose debris from the components and water surface.
5. Using a sediment probe such as a Sludge Judge®, measure the depth of sediment that has collected in the sump of the vessel.
6. On the Maintenance Log (see page 9), record the date, unit location, estimated volume of floatables and gross debris removed, and the depth of sediment measured. Also note any apparent irregularities such as damaged components or blockages.
7. Securely replace the grate or lid.
8. Take down safety equipment.
9. Notify Hydro International of any irregularities noted during inspection.

Floatables and Sediment Clean Out

Floatables clean out is typically done in conjunction with sediment removal. A commercially or municipally owned sump-vac is used to remove captured sediment and floatables (Fig.5).

Floatables and loose debris can also be netted with a skimmer and pole. The access port located at the top of the manhole provides unobstructed access for a vactor hose and skimmer pole to be lowered to the base of the sump.

Scheduling

- Floatables and sump clean out are typically conducted once a year during any season.
- Floatables and sump clean out should occur as soon as possible following a spill in the contributing drainage area.

Fig.4 Floatables are removed with a vactor hose (First Defense model FD-4, shown).

Recommended Equipment

- Safety Equipment (traffic cones, etc)
- Crow bar or other tool to remove grate or lid
- Pole with skimmer or net (if only floatables are being removed)
- Sediment probe (such as a Sludge Judge®)
- Vactor truck (flexible hose recommended)
- First Defense® Maintenance Log

Floatables and sediment Clean Out Procedures

1. Set up any necessary safety equipment around the access port or grate of the First Defense® as stipulated by local ordinances. Safety equipment should notify passing pedestrian and road traffic that work is being done.
2. Remove the grate or lid to the manhole.
3. Without entering the vessel, look down into the chamber to inspect the inside. Make note of any irregularities.
4. Remove oil and floatables stored on the surface of the water with the vactor hose (Fig.5) or with the skimmer or net (not pictured).
5. Using a sediment probe such as a Sludge Judge®, measure the depth of sediment that has collected in the sump of the vessel and record it in the Maintenance Log (page 9).
6. Once all floatables have been removed, drop the vactor hose to the base of the sump. Vactor out the sediment and gross debris off the sump floor (Fig.5).
7. Retract the vactor hose from the vessel.
8. On the Maintenance Log provided by Hydro International, record the date, unit location, estimated volume of floatables and gross debris removed, and the depth of sediment measured. Also note any apparent irregularities such as damaged components, blockages, or irregularly high or low water levels.
9. Securely replace the grate or lid.

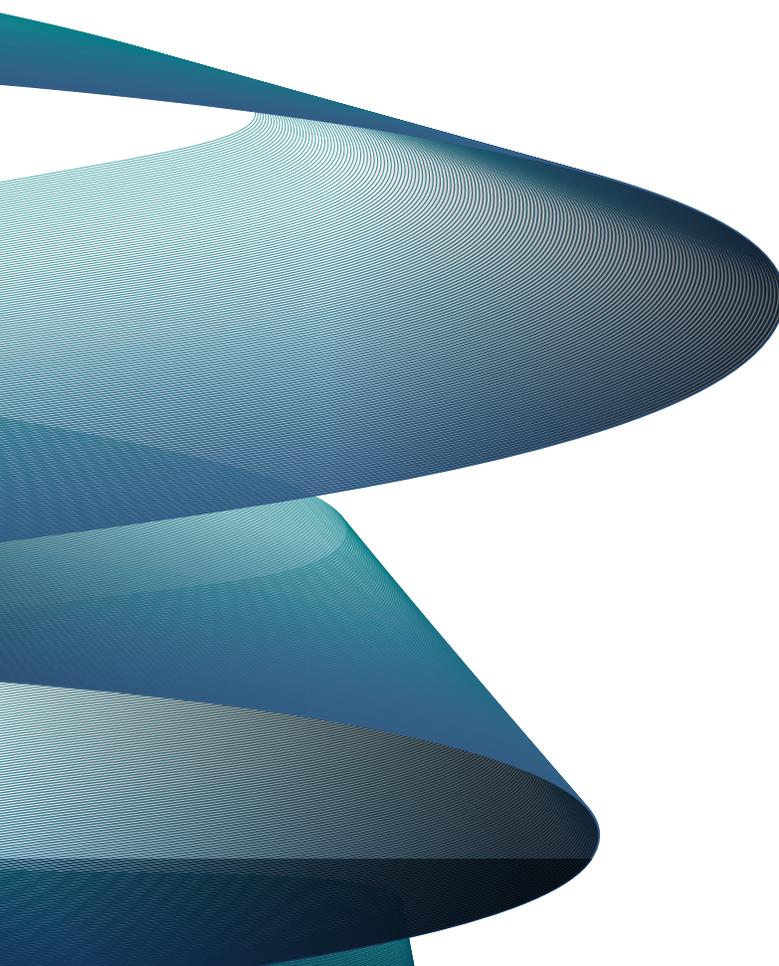

Fig.5 Sediment is removed with a vactor hose (First Defense model FD-4, shown).

Maintenance at a Glance

Inspection	- Regularly during first year of installation - Every 6 months after the first year of installation
Oil and Floatables Removal	- Once per year, with sediment removal - Following a spill in the drainage area
Sediment Removal	- Once per year or as needed - Following a spill in the drainage area

NOTE: For most clean outs the entire volume of liquid does not need to be removed from the manhole. Only remove the first few inches of oils and floatables from the water surface to reduce the total volume of liquid removed during a clean out.
